

**Biennial Convention 2009**

**Go for Gold**

**19–22 April 2009 • Sydney**

Institute of Actuaries of Australia

# **Dealing with Excessive Concentration to Stocks in Small Markets**

**Chris Condon**

## Should this drive your investments?

Nortel → 27% of TSE300

Vodafone → 12% of FTSE100

Nokia → 73% of Finnish index

BHP+Rio → 16% of ASX200 (May08)

Westfield → 51% of AREIT200

## How have we got here?

CAPM pseudo-science  
+  
pragmatism or laziness

Capitalisation  
weighted  
indices

Nutty benchmarking +  
over specialisation +  
business risk mgmt

Obsessive focus on  
tracking error,  
an irrelevant risk metric

Familiarity, patriotism,  
tax, costs, currency,  
liability-matching etc

Home  
country  
bias

## My questions

- How much single company concentration is acceptable in a total wealth portfolio?
- How can this be achieved?

## Soft issues

- Does diversity of business operations matter?
- Does one group strategy and one senior management weaken operational diversity?
- Does diversity of operations across industries matter?
- Does one share price matter? Does this affect analysts' behaviour? Does it create model risk?

## “Idiosyncratic shock” defined

- Negative contribution to total return attributable to any one stock
- Estimated in the paper:
  - using an arbitrary evaluation period (say 3 months)
  - ignores correlation effects
  - assumes normal distribution
  - function of dominating stock’s weight in total portfolio and its volatility

## Example: BHP

- Monthly return volatility: 6.9% (Apr00 – Jun08)
- Assuming serial independence  $\rightarrow$  12%pq
- BHP weight in index: 12.6%
- Australian equities allocation: 40%
- 2 standard deviation  $\rightarrow$  1.2% shock across whole fund

## If BHP and Rio Tinto merged

- Combined weight in index: 16%
- 6.4% of total portfolio
- 2 standard deviation  $\rightarrow$  1.7% shock across whole fund
- Virtual wipe-out (ala Lehmans)  $\rightarrow$  6.4% of total portfolio!  
(The paper was written pre Lehman's collapse)

## Acceptable idiosyncratic risk

- If acceptable idiosyncratic shock is 1%
- Then maximum allocation to dominant company  
→ 4% of total portfolio
- Or 10% of Australian equities allocation
- Based on 12% volatility per quarter and 2 standard deviation event
- Implies losing 4% of wealth due to failure of one company is just acceptable
- Open question: Are there better ways to specify this risk?

## Mandating multiple investment managers

- Assume:
  - Portfolio of independent managers with different approaches
  - All managers assumed to have skill
  - Liberal mandates should extract maximum benefits from skill
  - Portfolios are independent, i.e. no overlay on manager portfolios
- → the highest stock weighting in the aggregate portfolio will have a probability distribution

## Rule of thumb

Rule of thumb:

95% of the time the total portfolio will hold no more than 3% in any one stock as a result of the independent actions of investment managers

Consistent with the occasional occurrence of 4% of the portfolio held in just one stock

Ignores other sources of idiosyncratic risk (e.g. holding the company's debt as well as equity)

## Model

- For each manager use Monte Carlo simulation to rank stocks
- All pair-wise correlations between manager stock ranks assumed to be 0.4
- Build portfolio based on various portfolio construction rules
- Graph the distribution of highest stock weight in the total portfolio

## Common parameters

- 35% in Australian equities; 10 managers
- 38% in global equities; 7 managers
- Managers constrained to 15% to one stock and no shorting
- Global managers buy Australian stocks an absolute allocation. Index weights in world index small and ignored.
- Restrict pool of Australian stocks to 80 largest

## Strategy 1 (base case)

- All domestic managers adopt a high conviction, index-aware approach
- 20 stocks are held in the portfolio
- Five highest ranked stocks held 5 percentage points overweight\*
- Five lowest ranked stocks held 5 percentage points underweight\*
- The same bet to all other stocks to complete the portfolio (see page 13 of the paper)

\* subject to mandate constraints of absolute weight <15% and no shorting

## Strategy 1 (base case)

#1; Strategy 1: Relative to ASX 300 Index; High conviction; Max bets= 5%/ -5%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

4% chance of highest stock concentration > 3%  
→ not undue risk based on rule of thumb

## Strategies

Seven different strategies for domestic managers

1. High conviction index-aware managers (base case)
2. Traditional index-aware managers
3. Extremely concentrated index-aware managers
4. Closet indexers
5. Diversified index-agnostic managers
6. High conviction index-agnostic managers
7. Extremely concentrated index-agnostic managers

## Strategies defined

<i>Strategy:</i>	1	2	3	4	5	6	7
<b>Domestic managers</b>							
<b>Index-aware or agnostic</b>	index-aware	index-aware	index-aware	index-aware	agnostic	agnostic	agnostic
<b>Mandate risk</b>	high conviction	traditional	extreme	closet indexers	diversified	high conviction	extreme
<b>Stocks in portfolio</b>	20	30	15	45	40	20	15
<b>Limits<sup>1</sup></b>	15% 0%	15% 0%	15% 0%	15% 0%	15% 0%	15% 0%	15% 0%
<b>Bet<sup>2</sup></b>	+5% -5%	+3% -3%	+7% -7%	+1% -1%	4% 0%	7% 0%	10% <sup>3</sup> 0%
<b># in hi/lo group<sup>4</sup></b>	5/5	5/5	5/5	10/10	5/0	5/0	5/0
<b>Global managers</b>							
<b># domestic stocks</b>	1	1	3	2	1	1	3
<b>Weight to each</b>	3%	5%	7%	2%	4%	5%	7%

## Strategy 2: Traditional index-aware

#2; Strategy 2: Relative to ASX 300 Index; Traditional; Max bets= 3%/-3%  
Stocks in universe=80; Stocks in portfolio= 30; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

**15% chance of idiosyncratic risk!!**

**More risky than using high conviction managers**

## Strategy 3:

# Extreme high conviction index-aware

#3; Strategy 3: Relative to ASX 300 Index; Extreme; Max bets= 7%/-7%  
Stocks in universe=80; Stocks in portfolio= 15; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

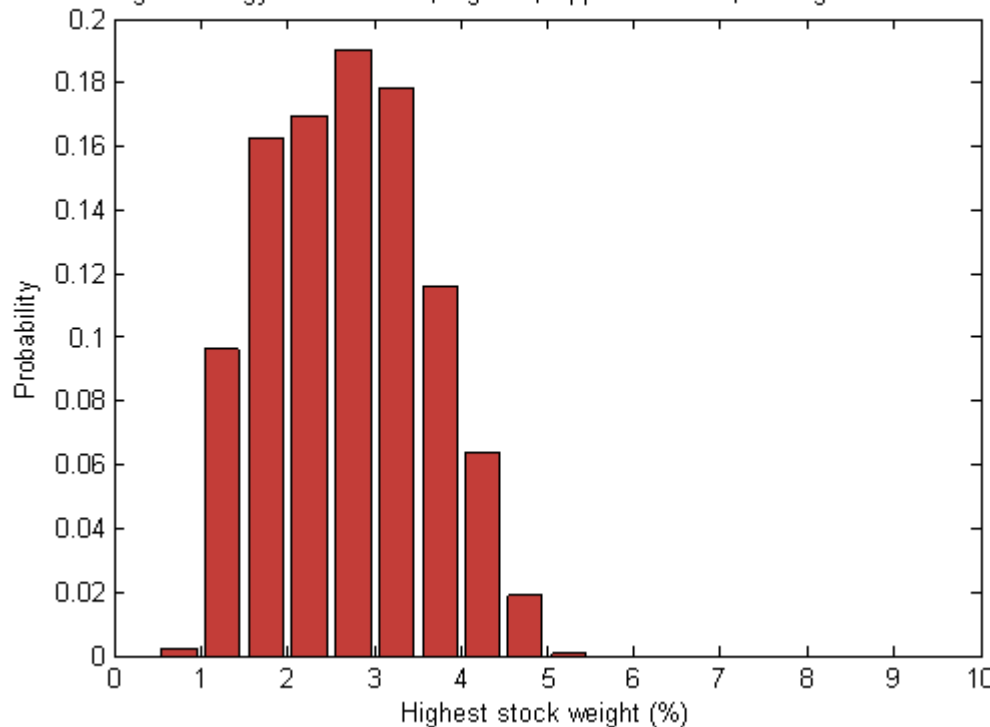

Even less risky. Tiny chance of idiosyncratic shock.

## Strategy 4: Closet indexing

#4; Strategy 4: Relative to ASX 300 Index; Closet indexing; Max bets= 1%/-1%  
Stocks in universe=80; Stocks in portfolio= 45; # in high/low ranked groups=10/10  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

Whopping 38% chance of highest allocation >3%.  
Awful idiosyncratic risk.

## Strategy 5: Diversified index-agnostic

#5; Strategy 5: Index agnostic; Diversified; Weight to high ranked stocks= 4%  
Stocks in universe=80; Stocks in portfolio= 40; # in high/low ranked groups=5/0  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

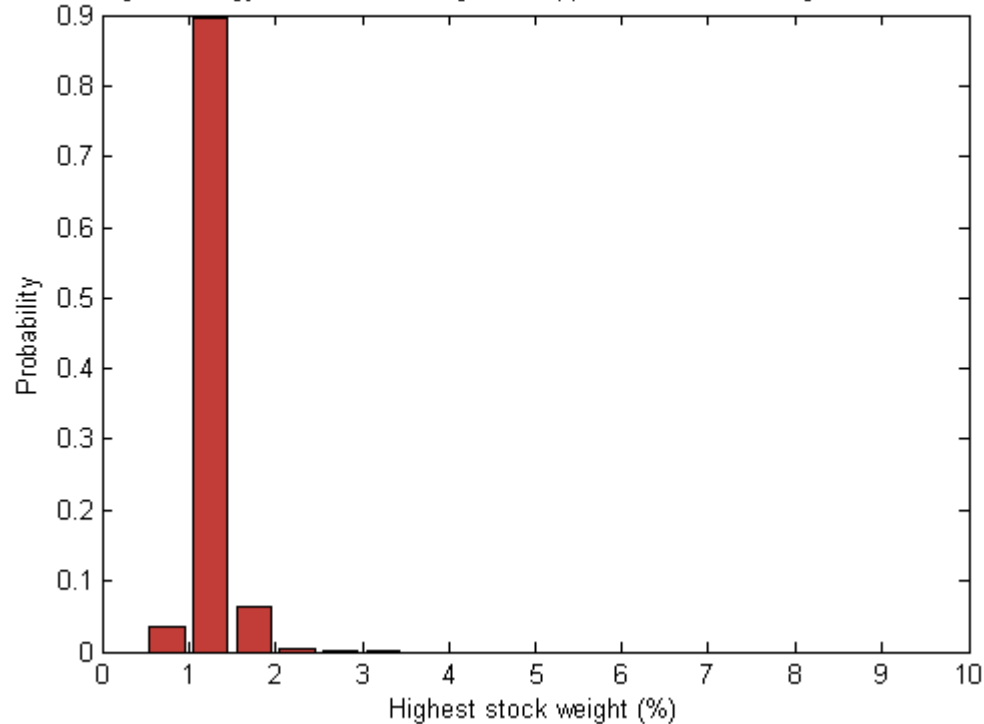

Virtually no idiosyncratic risk.  
But huge tracking error and peer risk.

## Strategy 6: High conviction index-agnostic

#6; Strategy 6: Index agnostic; High conviction; Weight to high ranked stocks= 7%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/0  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

Ditto to Strategy 5; very low idiosyncratic risk.

## Strategy 7: Extreme index-agnostic

#7; Strategy 7: Index agnostic; Extreme; Weight to high ranked stocks= 10%  
Stocks in universe=80; Stocks in portfolio= 15; # in high/low ranked groups=5/0  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.4

Some chance of idiosyncratic risk,  
but lower than index-aware approaches

## Impact of fewer managers Strategy 1 with 4 domestic managers

#8; Strategy 1: Relative to ASX 300 Index; High conviction; Max bets= 5%/-5%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/5  
Manager strategy: 4 domestic, 3 global; Upper limit 15%; Manager correlation 0.4

13% chance of highest stock weight  $> 3\%$   
→ manager diversification is important

## Traditional index-aware with 4 managers

#9; Strategy 2: Relative to ASX 300 Index; Traditional; Max bets= 3%/-3%  
Stocks in universe=80; Stocks in portfolio= 30; # in high/low ranked groups=5/5  
Manager strategy: 4 domestic, 3 global; Upper limit 15%; Manager correlation 0.4

20% chance of idiosyncratic risk. Awful.

## Impact of removing 15% limit to one stock

#10; Strategy 1: Relative to ASX 300 Index; High conviction; Max bets= 5%/-5%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit overridden; Manager correlation 0.4

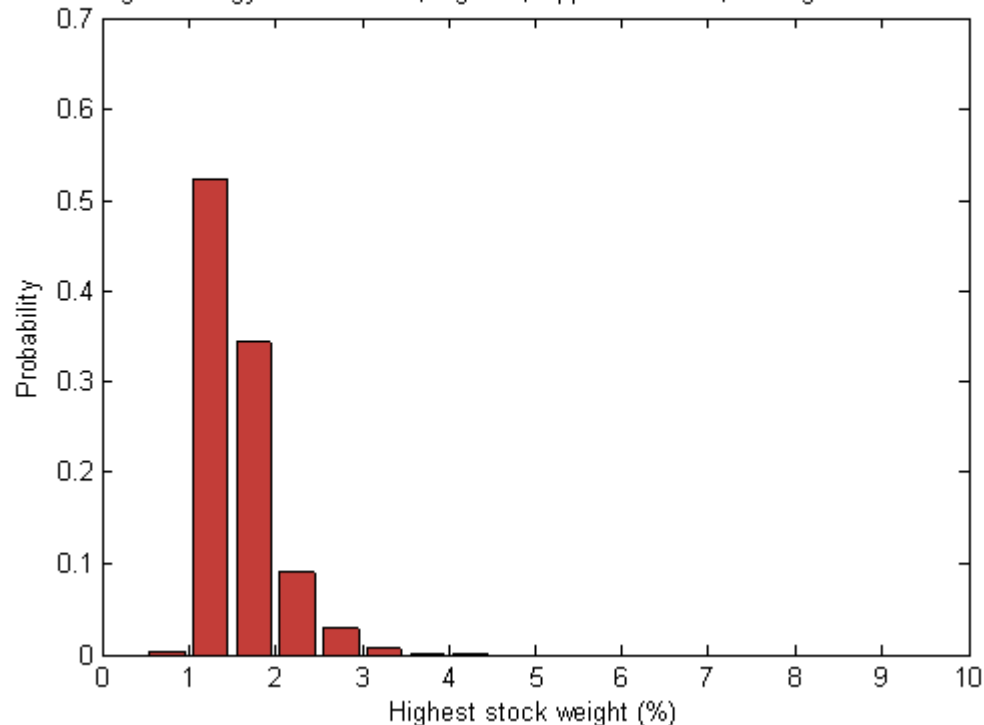

15% limit to one stock helps, but not much

## Lower (12%) limit to one stock

#11; Strategy 1: Relative to ASX 300 Index; High conviction; Max bets= 5%/-5%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit 12%; Manager correlation 0.4

Reduces chance of idiosyncratic risk from 4% to 1%.  
But managers would be forced to underweight BHP!

## The 15% limit helps with fewer managers

#12; Strategy 2: Relative to ASX 300 Index; Traditional; Max bets= 3%/-3%  
Stocks in universe=80; Stocks in portfolio= 30; # in high/low ranked groups=5/5  
Manager strategy: 4 domestic, 3 global; Upper limit overridden; Manager correlation 0.4

Without a limit chance of idiosyncratic risk (in #9)  
rises from 20% to 36%

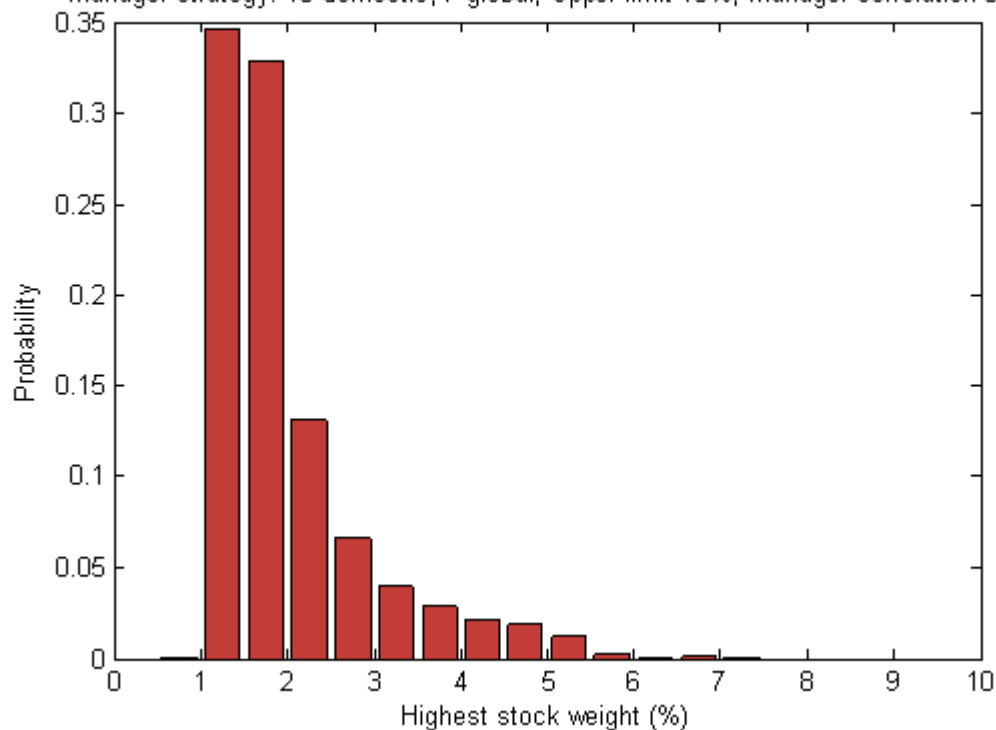

## Importance of manager diversification

(Correlation of ranking 0.4 → 0.8)

#15; Strategy 1: Relative to ASX 300 Index; High conviction; Max bets= 5%/-5%  
Stocks in universe=80; Stocks in portfolio= 20; # in high/low ranked groups=5/5  
Manager strategy: 10 domestic, 7 global; Upper limit 15%; Manager correlation 0.8

Considerable impact:

chance of idiosyncratic risk goes from 4% to 13%

## How to ameliorate idiosyncratic risk

- 1. Reduce allocation to domestic equities**
2. Live with it
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- Obvious and effective
- Reasons for home country bias (e.g. peer risk) tend to trump this approach

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
- 2. Live with it**
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- If most managers loaded up on the stock, then it could be for good reasons
- Need
  - many managers
  - none dominating
  - different approaches and styles
  - high conviction, if not index agnostic

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
- 3. Impose maximum absolute limits in mandates**
4. Improve manager diversification
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- Limited marginal use when using many managers
- Necessary if not using many managers

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
3. Impose maximum absolute limits in mandates
- 4. Improve manager diversification**
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- The more managers the better
- Provided they are differentiating
- But too many index-aware managers will tend the total portfolio to the index

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
- 5. Use index-agnostic managers**
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- Most effective
- Hard to find
- Beware of lip-service

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
5. Use index-agnostic managers
- 6. Manage maximum individual concentration at total portfolio**
7. Use capitalisation-capped indices
8. Use non-capitalisation weighted indices

- Possible overlays:
  - leave manager portfolios unchanged and short excessive holdings
  - instruct managers to sell down
  - dynamically budget manager mandates
- All are unattractive:
  - operational risk
  - complexity
  - unwanted manager behaviour

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
- 7. Use capitalisation-capped indices**
8. Use non-capitalisation weighted indices

- Need clear and transparent index rebalancing rules
- Requires clear understanding of manager behaviours
- Custom index to be built
- Could be effective

## How to ameliorate idiosyncratic risk

1. Reduce allocation to domestic equities
2. Live with it
3. Impose maximum absolute limits in mandates
4. Improve manager diversification
5. Use index-agnostic managers
6. Manage maximum individual concentration at total portfolio
7. Use capitalisation-capped indices
- 8. Use non-capitalisation weighted indices**

- E.g. fundamental indexing
- Unlikely to be superior to capitalisation-capped index (in terms of objectivity, transparency and simplicity)

## Conclusions

Real issue for Australian investors

Most effective solutions:

- reduce allocation to Australian equities
- use index agnostic managers
- use capped index for benchmark
- use many different, high conviction managers

These require varying levels of bravery!
